

# Professional Intranet Applications

Intranet applications use essentially the same technology as Internet web applications, but differ in business goals, and, sometimes, budgets and schedules. Intranet business applications use the local-area network (LAN) infrastructure within a company along with Internet Web technology to provide high-performance software solutions.

Intranet applications are a turn-key alternative to larger more expensive content management systems. They enable your company to create, update and complete electronic forms on-line then route them to proper destinations for approval and completion.

In addition, intranet applications provide additional integrated workflow modules such as Company Procurement, Time and Attendance and Cash Settlement, which evolve into an enterprise-wide platform automation solution everyone in your company can use to further reduce many expensive manual processes. Why use intranet applications?

A well designed and maintained intranet application is becoming a critical resource for organizations large and small.

The main reason we started to build intranet applications back in 2001 was because we've realized the advantages this kind of software solutions can offer to the medium and large business.

Let's think for example at the information that can be managed by several computers at the same time, the updates that only have to be applied to one computer instead of all the computers on which the intranet applications are running and the ease of connecting intranet applications to web applications. Well, it's not hard to understand why many companies prefer this kind of software solutions against the stand alone, install on each computer kind of software.

IT-NET-DESIGN Ltd., a professional web solutions provider company delivers, at the moment, a two in one stable intranet application which will help restaurant, store and/or warehouse owners to keep real time track of their inventory and sales.

An intranet application will do more with less!
